Marks Obtained : 40

Section 1 : Coding

1. Problem Statement

Arjun is working on a mathematical tool to manipulate lists of numbers. He needs a program that reads a list of integers and generates two lists: one containing the squares of the input numbers, and another containing the cubes. Arjun wants to use lambda functions for both tasks.

Write a program that computes the square and cube of each number in the input list using lambda functions.

Input Format

The input consists of a single line of space-separated integers representing the list of input numbers.

Output Format

The first line contains a list of the squared values of the input numbers.

The second line contains a list of the cubed values of the input numbers.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 1 2 3

Output: [1, 4, 9]

[1, 8, 27]

Answer

```
inp_list = list(map(int, input().split()))
```

```
square_nums = list(map(lambda x: x ** 2, inp_list))
```

```
cube_nums = list(map(lambda x: x ** 3, inp_list))
```

```
print(square_nums)
```

```
print(cube_nums)
```

Status : Correct

Marks : 10/10

2. Problem Statement

Amrita is developing a password strength checker for her website. She wants the checker to consider the length and the diversity of characters used in the password. A strong password should be long and include a mix of character types: uppercase, lowercase, digits, and special symbols.

She also wants the feedback to be user-friendly, so she wants to include the actual password in the output. Help Amrita finish this password checker using Python's built-in string methods.

Character Types Considered:

Lowercase letters (a-z) Uppercase letters (A-Z) Digits (0-9) Special characters (from string.punctuation, e.g. @, !, #, \$)

Input Format

The input consists of a single string representing the user's password.

Output Format

The program prints the strength of the password in this format:

If the password length < 6 characters or fewer than 2 of the 4 character types, the output prints "<password> is Weak"

If password length ≥ 6 and at least 2 different character types, the output prints "<password> is Moderate"

If Password length ≥ 10 and all 4 character types present, the output prints "<password> is Strong"

Refer to the sample output for formatting specifications.

Sample Test Case

Input: password123

Output: password123 is Moderate

Answer

```
import string
```

```
password = input()
length = len(password)
```

```
has_lower = 0
has_upper = 0
has_digit = 0
has_special = 0
```

```
for char in password:
    if char.islower():
        has_lower = 1
    elif char.isupper():
        has_upper = 1
    elif char.isdigit():
```

```
has_digit = 1
elif char in string.punctuation:
    has_special = 1

types_count = has_lower + has_upper + has_digit + has_special

if length < 6 or types_count < 2:
    strength = "Weak"
elif length >= 10 and types_count == 4:
    strength = "Strong"
else:
    strength = "Moderate"

print(f"{password} is {strength}")
```

Status : Correct

Marks : 10/10

3. Problem Statement

Develop a text analysis tool that needs to count the occurrences of a specific substring within a given text string.

Write a function `count_substrings(text, substring)` that takes two inputs: the text string and the substring to be counted. The function should count how many times the substring appears in the text string and return the count.

Function Signature: `count_substrings(text, substring)`

Input Format

The first line of the input consists of a string representing the text.

The second line consists of a string representing the substring.

Output Format

The output should display a single line of output containing the count of occurrences of the substring in the text string.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: programming is fun and programming is cool
programming

Output: The substring 'programming' appears 2 times in the text.

Answer

```
def count_substrings(text, substring):  
    count = 0  
    start = 0  
  
    while start < len(text):  
        index = text.find(substring, start)  
        if index == -1:  
            break  
        count += 1  
        start = index + 1  
  
    return count  
text = input()  
substring = input()  
result = count_substrings(text, substring)  
print(f"The substring '{substring}' appears {result} times in the text.")
```

Status : Correct

4. Problem Statement

Implement a program for a retail store that needs to find the highest even price in a list of product prices. Your goal is to efficiently determine the maximum even price from a series of product prices. Utilize the max() inbuilt function in the program.

For example, if the prices are 10 15 24 8 37 16, the even prices are 10 24 8 16. So, the maximum even price is 24.

Input Format

The input consists of a series of product prices separated by a space.

The prices should be entered as a space-separated string of numbers.

Output Format

If there are even prices in the input, the output prints "The maximum even price is: " followed by the maximum even price.

If there are no even prices in the input, the output prints "No even prices were found".

Refer to the sample output for formatting specifications.

Sample Test Case

Input: 10 15 24 8 37 16

Output: The maximum even price is: 24

Answer

```
max_even = None
```

```
prices = input().split()
```

```
for price in prices:
    price = int(price)
    if price % 2 == 0:
        if max_even is None:
            max_even = price
        else:
            max_even = max(max_even, price)
```

```
if max_even is not None:
    print(f"The maximum even price is: {max_even}")
else:
    print("No even prices were found")
```
